

1. Comprehensive Introduction to Digital Distributed Ledgers

Distributed ledgers have the potential to transform the way people and organizations handle identity, transaction, and debt information. I have heard the terms "distributed ledger" and "mutual distributed ledger" and "shared ledger" and "digital ledger" and "global digital distributed ledger" used interchangeably. I will use the term digital distributed ledger.

The purpose of this module is to give you a good, solid working knowledge of digital distributed ledgers.

1.1. Description of a digital distributed ledger

A digital distributed ledger is an indestructible and un-editable decentralized computer record, or ledger. A digital distributed ledger provides a full and complete history of transactions in that ledger. Ledgers can be as public and open or private and limited as the use case demands. Ledgers can be permissioned or permissionless in determining who can add new transactions. Different approaches can be used to determine how new transactions are authorized (proof-of-stake, proof-of-work, consensus, identity mechanisms) before they can update the ledger. Ledgers can be interlinked with one or more other ledgers.

1.2. Blockchain

The key innovation that enables computerized digital distributed ledgers is the blockchain technology¹. Blockchain technology is used to maintain what amounts to a continuously growing list of translational data records hardened against tampering and revision, even by operators, using advanced cryptography (basically, cryptographic mathematics). Blockchain is a consensus algorithm.

As Gabriel Tumlos of KPMG put it in his paper *Blockchains, Distributed Ledgers in Finance and Accounting*, "Blockchains introduced a trust-minimizing transactional platform that all but eliminates the need for a vulnerable third party and allows accounting systems to take their logical next step."

1.3. Hashgraph

An alternative consensus algorithm to blockchain for implementing digital distributed ledgers is hashgraph. This article, *Blockchain Just Became Obsolete: the Future is Hashgraph*², helps you understand the difference between blockchain and hashgraph. In particular, this 10 minute video³ referenced in the article is very helpful.

³ YouTube, *Hashgraph Introduction*, <https://youtu.be/ZrFrXFdRW4k>

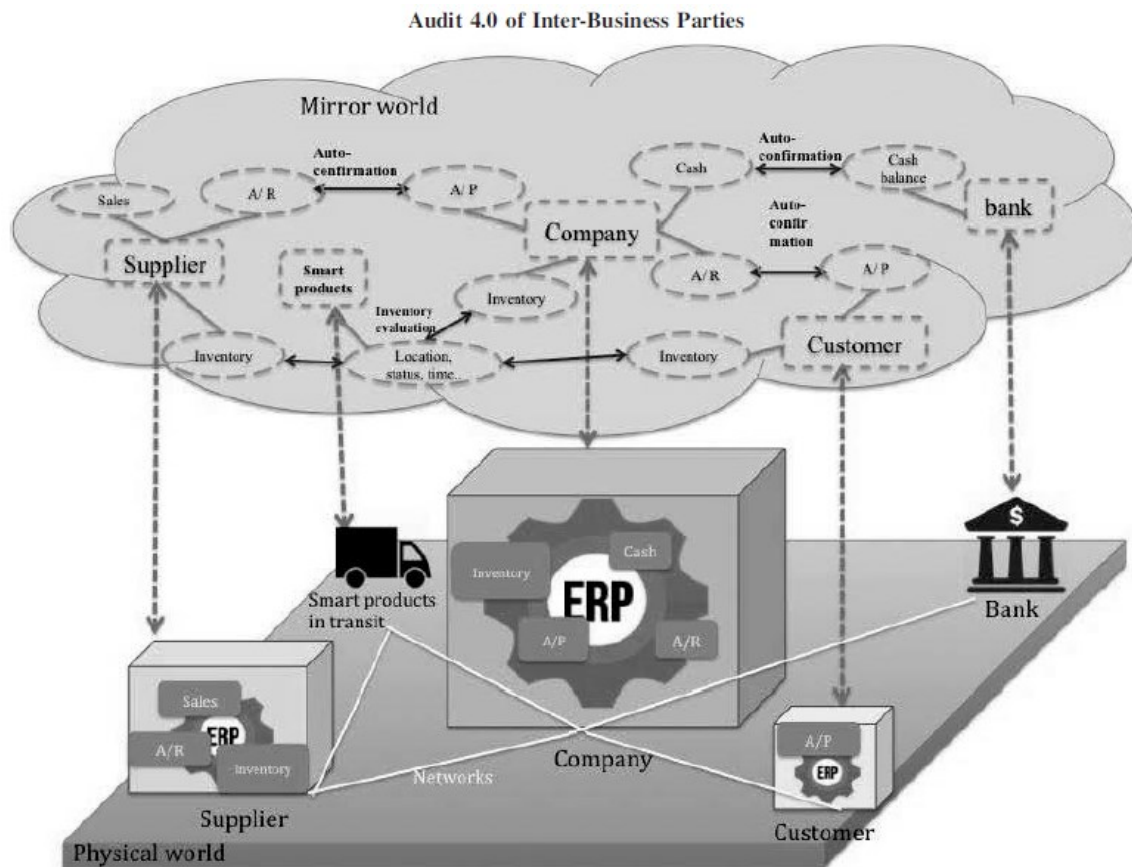

1.4. Triple entry accounting system

The idea of triple entry accounting was introduced by Ian Grigg in a paper, *Triple Entry Accounting*⁴.

With triple entry accounting, both parties to a transaction would complete a transaction and simultaneously record information about that transaction in a shared ledger. Once that happens, it's necessary to ensure that that information about that transaction can't be changed.

1.5. Real-time audit or continuous audit

A triple entry accounting system opens the possibility of the real-time audit⁵ or the continuous audit. In their paper *Imagineering Audit 4.0*⁶, Jun Dai and Miklos Vasarhelyi of Rutgers University provide a comprehensive description of how a real-time audit works including the diagram below:

1.6. Use cases for digital distributed ledgers

What can digital distributed ledgers be used for⁷? This video mentions the following use cases:

- Regulatory records
- Delivery records
- Chain of custody
- Property titles
- Know your customer
- Digital rights management
- Loyalty management
- Motor insurance
- Proof of authenticity
- Account portability
- Anti-money laundering
- Peer-to-peer lending
- Personal insurance
- Corporate credit
- Trading records

There are likely many other uses for a digital distributed ledger.

1.7. Financial report as a transaction

Don't limit yourself by thinking that a "transaction" is an accounting transaction such as an invoice. While transactions can be recorded, so can events, circumstances, and other phenomenon that affect, say, a business during a period. That sounds a lot like the sort of information from a financial report. A report is a transaction. The "payload" of the transaction is the information in the report itself. XBRL-based digital general purpose financial reports, say to a regulator like the Securities and Exchange Commission, are really transactions that hold complex information structures about the financial condition and financial position of an economic entity.

What XBRL brings to the table is an ability to agree on and document the relations between the reported facts in the complex transactions we refer to as financial reports. But XBRL can also be used to make sure that smaller transactions that go into these ledgers adhere to agreed upon business rules. This keeps information within those digital distributed ledgers correct.

If digital distributed ledgers are used to their full potential, it could enable a fundamental shift in the way economic entities transact business with one another. How will this impact the role of accountants and auditors? Time will tell.

1.8. *Impact of distributed ledgers on accounting*

Hitendra Patil summarized 22 ways distributed ledger technology and blockchain will change the accounting profession⁸. While I do not agree with everything on the list, the list is worth considering:

1. Eventually, accounting firms will go away, just like bookstores.
2. An accountant will NOT become extinct. She will be just doing something (absolutely, totally) different (and surely more **valuable** work).
3. Auditors, rather the current way audit processes work, will go away too.
4. This is because “audit” will be easy and highly cost-effective with access to a public shared ledger.
5. A client will NOT provide information, data and documents to the accountant – ever.
6. Gone forever will be the days when a client sent a shoebox full of receipts to the accountant.
7. Client’s accounts books, and the blockchains – the shared ledgers – will get created constantly and automatically, as and when transactions are taking place. Sometimes even before they happen!
8. Just like the doctors and nurses who monitor the patients’ health, accountants will monitor financial health of clients, but online, in real time and almost always remotely.
9. Clients will NOT need to file tax returns. This is because the government will have the information already and the government will refund the extra taxes deducted from financial transactions. People won’t be able to avoid or evade or pay fewer taxes than they owe – ever. So, people will NOT ask accountants to prepare tax returns. Instead, they will seek advice to “prepare for” optimized tax deductions.
10. Clients will NOT run out of cash to run their businesses – at least not fast. This is because banks will release cash automatically into their checking accounts when needed, as financing on their “preauthorized linked assets” will be created automatically, online, in real time.
11. Accountant will tell clients the precise time when they will lose those assets if the bank keeps putting cash into their checking account.
12. Clients can see the future of their business. Every day. Every minute. At the speed their business operates, their accountant will show them the balance sheet of future months and years.
13. If a client’s business has started to go downhill, his accountant will tell him precisely how many days or months he has before he will lose everything.
14. If a client’s business is on an upswing, she will know precisely when will it reach stagnation stage based on performance of her industry peers and as the impact of new technologies and regulations kicks in. In other words, her

⁸ Hitendra Patil, CPA Trendlines, *22 Ways Blockchain Will Change the Accounting Profession Forever*, <http://cpatrendlines.com/2017/07/03/22-ways-blockchain-will-impact-accounting-profession/>

accountant will tell her how much time she has to create a new product or service to keep the upswing intact.

15. Clients will make and receive fewer payments. This is not because their business is slow but because vendors and customers will settle monetary transactions on net basis, not on gross basis – because everyone’s accounts books will be networked.
16. Clients’ books will tell them, automatically, who are their “currently good” customers who are likely to be bad ones in the near future, even when revenue from them is growing, as their books will be synced with their customers’ books.
17. Client’s books will also tell them, automatically, who are their “currently bad” customers who are likely to be good ones in the near future, even when revenue from them is actually reducing, as their books will be synced with their customers’ books.
18. Clients’ books will tell them automatically which of their customers and vendors are likely to go out of business and by when, because their books will be networked. And of course, they too will know, online, in real time, if their accountant’s business is doing well or bad.
19. Hold on! Clients’ accounting is NOT going to be emotionless robotics. Just the data and information handling will be robotic. Clients will still have their accountants as their even more trusted advisor, in the flesh.
20. Clients WON’T have to make appointments with their accountants anymore. Clients can ask an accountant or a financial advisor – online or by phone, in real time – by picking the one they want from several out there. Clients won’t even have to send any accounting data to them. Clients will just share it with accountants while the online session lasts.
21. Today’s accountants will be tomorrow’s business strategists and growth directors for their clients.
22. And yes, there will be NO fees to be paid for “accounting.” Clients will pay their accountant only for use of her knowledge, experience and wisdom to help them navigate their business and financial situations.

While it is hard to say exactly which of these predictions will become reality and when; the list provides a clear understanding of the trajectory accounting, reporting, and auditing will take.

1.9. Implementing distributed ledgers

Key to implementing a distributed ledger appropriately is security⁹. But the security issues will be addressed. The following is a summary of additional resources that are helpful in understanding and implementing distributed ledgers:
